- ❑ Chapter 6 (section 1,2,3)

**Distributed Computing** Principles, Algorithms, and Systems  
Ajay D. Kshemkalyani and Mukesh Singhal

# Ordered Communication Hierarchy

# Bagrodia's Algorithm

## □ Assumptions:

- m RECV commands are always enabled (within scope of a construct)
- m SEND once enabled remain enabled before the send is executed
- m Process IDs can be used to break symmetry
- m Only one send command per process enabled.
- m It is possible to receive small protocol messages

# Binary Rendezvous

# Basic Idea

Figure 6.9: Messages used to implement synchronous order.  $P_i$  has higher priority than  $P_j$ . (a)  $P_i$  issues SEND( $M$ ). (b)  $P_j$  issues SEND( $M$ ).

(message types)

$M$ ,  $ack(M)$ ,  $request(M)$ ,  $permission(M)$

1.  $P_i$  wants to execute **SEND(M)** to a lower priority process  $P_j$ :

$P_i$  executes  $send(M)$  and blocks until it receives  $ack(M)$  from  $P_j$ . The send event **SEND(M)** now completes.

Any  $M'$  message (from a higher priority processes) and  $request(M')$  request for synchronization (from a lower priority processes) received during the blocking period are queued.

2.  $P_i$  wants to execute **SEND(M)** to a higher priority process  $P_j$ :

(a)  $P_i$  seeks permission from  $P_j$  by executing  $send(request(M))$ .

// to avoid deadlock in which cyclically blocked processes queue messages.

(b) While  $P_i$  is waiting for permission, it remains unblocked.

i. If a message  $M'$  arrives from a higher priority process  $P_k$ ,  $P_i$  accepts  $M'$  by scheduling a **RECEIVE(M')** event and then executes  $send(ack(M'))$  to  $P_k$ .

ii. If a  $request(M')$  arrives from a lower priority process  $P_k$ ,  $P_i$  executes  $send(permission(M'))$  to  $P_k$  and blocks waiting for the message  $M'$ . When  $M'$  arrives, the **RECEIVE(M')** event is executed.

(c) When the  $permission(M)$  arrives,  $P_i$  knows partner  $P_j$  is synchronized and  $P_i$  executes  $send(M)$ . The **SEND(M)** now completes.

3. **Request(M)** arrival at  $P_i$  from a lower priority process  $P_j$ :

At the time a  $request(M)$  is processed by  $P_i$ , process  $P_i$  executes  $send(permission(M))$  to  $P_j$  and blocks waiting for the message  $M$ . When  $M$  arrives, the **RECEIVE(M)** event is executed and the process unblocks.

4. **Message M** arrival at  $P_i$  from a higher priority process  $P_j$ :

At the time a message  $M$  is processed by  $P_i$ , process  $P_i$  executes **RECEIVE(M)** (which is assumed to be always enabled) and then  $send(ack(M))$  to  $P_j$ .

5. **Processing when  $P_i$  is unblocked:**

When  $P_i$  is unblocked, it dequeues the next (if any) message from the queue and processes it as a message arrival (as per Rules 3 or 4).

# Example

Figure 6.11: Examples showing how to schedule messages sent with synchronous primitives.
